Abstract

The outbreak of COVID-19 has increased the demand for new drug development. That has led to a growing interest in chemoinformatics, which is valuable information technology to predict chemical reactions. The use of enzymes as catalysts is gaining importance in terms of the environment and reaction efficiency. In order to predict the best enzyme to obtain the desired product, the target chemical equation is compared with typical chemical equations of enzymes classified by Enzyme Commission Number (EC number) using clustering. The EC number of the chemical equation that is evaluated to have the highest similarity is predicted.

1. Introduction

In recent years, enzymes are increasingly used as biocatalysts in the design and prediction of chemical reactions for green In recent years, enzymes are increasingly used as Diocatalysts in the design and prediction or cinemical reactions for green chemistry and efficiency. Therefore, it is becoming important to predict the most suitable enzyme for a chemical reaction by machine learning. The first step of this study, we make the machine learner learn the changes in physical and chemical property values from reactants to products in the chemical equations described in Enzyme Commission numbers (EC numbers). Next, the best enzymes to use for a target chemical equation is predicted as an EC number by learned machine learner. Finally, we consider the prediction accuracy of the learner.

Keywords: EC Number, Chemoinformatics, Feature Selection, Clustering

2. Chemoinformatics and Information Technology

Compounds

Various representations are used to handle chemical structures in computer as chemical structures in computer as chemoinformatics. This study uses a method quantifying physical/chemical characteristics.

Using RDKit [1], we calculate many type of compounds for machine learning

RDKit reads chemical structure information files obtained from databases and draws structural formula object. After that, Smiles or Characteristic values are calculated.

3. Proposed Method

3.1 Method Outline

from rdkit import Chem Xylitol = Chem.MolFromMolFile('Xylitol.mol') Xylitol Structural formula object Text representation Chem.MolToSmiles(Xylitol) (Smiles) OC[C@H](O)[C@@H](O)[C@H](O)CO from rdkit.Chem import Descriptors Descriptors.MolWt(Xylit Calculate characteristics value (molecular weight)

This study compares the structural changes of a target chemical equation and EC number chemical equations. Finally, the optimal EC number is predicted for the target. we assume that, if the target chemical structural change from reactant to product is similar to an EC chemical equation structural change, the same EC enzymes can be used to target chemical reaction. This is based on the concept of molecular similarity used in chemistry [2].

Therefore, when an EC chemical equation structural change is similar for target, this EC number is predicted as the

Structural change = Amount of changes in characteristic values from reactants to products

Assumptions: Structural changes of the target and EC chemical equation are similar. Target product can be obtained by using the EC enzymes(concept of molecular similarity).

Reactant + Reactant -Target Product A

Characteristic value changes (descriptor): Feature Vector
V1 = (X, Y, Z, • Mol Weight X, Charge Y, Hydrophobicity Z, ...

3.2 Features Representing Structural Change

Previous studies [3]: Classification of EC chemical equation (focusing on fingerprint changes)

 $EC X.X.X.X : RCT1 + RCT2 \rightarrow PDT1 + PDT2$ $\rightarrow RFP = FP_{PDT1+PDT2} - FP_{RCT1+RCT2}$

FP: Fingerprints of each compound

One kind of fingerprint have a limit in representing the structural changes. (Many fingerprints have been developed)

Proposed method: Amount of change in characteristic values

Characteristic values of n descriptors for each reaction equation: cv_i

 $cv_j = (PD_1 + PD_2) - (RT_1 + RT_2)$ (j = 1, 2, ..., n)(RT_i (PD_i): Characteristic value of reactant i (product j)

Feature vectors for each chemical equation: $DF_i(i = 1, 2, ..., m)$

 $DF_i = (cv_{i1}, cv_{i2}, \cdots, cv_{ij}, \cdots, cv_{in})$

Present the EC number of the DF_i most similar to the Target

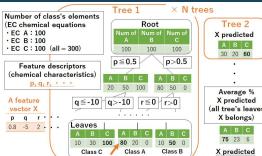

Desc 1 Desc n cv_{T1} cv_{T2} cv_{Tr} DF_1 cv_{11} cv_{12} cv_{21} cv_{22} cv_{2n}

Many type of physical/chemical property value changes describe structural changes

(RDKit has 208 descriptors)

Some studies mainly use reactions that occur in nature as described in KEGG [4]. This study is significant in terms of making predictions for experimental reactions that are not described.

3.3 Predicting Method (Random Forests [5])

X predicted Class A

thresholds. Where a descriptor is used and how its threshold is determined. the bias of the class distribution when splitting data from one node to two lower nodes. The descriptor location and threshold are determined so that the information gain of each node is maximized. The class prediction probability of the feature vector is obtained by the average class ratios of

Tuning Parameters Num of Descriptors Tree depth (root → leaf) Num of Tree

Random Forests uses many trees. Each EC equation's feature vector go to a leaf from root classified by descriptor depends on the information gain about the leaf nodes that it belongs to in each

4.4. EC 4th Number Prediction Using Clustering

used.
For 2 targets of EC 3.1.1.3, five EC 3.1.1.3 equations belonged to other cluster.
While the EC first to three numbers classify enzymes

according to enzyme properties, the fourth number classifies by their name. We will develop a method that can successfully predict up to the fourth number.

In the third number of EC 3 class prediction, there were some classes with high accuracy and others with low accuracy. It is necessary to develop a feature selection method to obtain a certain level of prediction accuracy for all classes or add new features. In addition, this study did not take into account coefficients of each term in the chemical equation.
The ratio of compounds need to be incorporate in the future.

6. Conclusion

This study proposed a method to predict the second and third number of the EC 3 class target chemical equation using random forests. Future work focuses on developing a

prediction method of other EC classes (EC 1,2,4,5,6 and 7) and a method based on a classification rules that introduces a clustering method for EC
